Are retailers leveraging in-store analytics?

An exploratory study

Abstract

Purpose – The purpose of this study is to analyse the level of adoption of *in-store analytics* by brick-and-mortar retailers. *Web analytics* technology has been widely adopted by online retailers, and the technology to gather similar information in physical stores is already available. This study explores how such technology is valued and adopted by retailers.

Design/methodology/approach – This study is based on interviews and a focus group of 21 retail executives using a semi-structured interview methodology. An in-store analytics service was defined, along with specific key performance indicators (KPIs) and use cases to structure respondents' feedback.

Findings – Although noteworthy differences have been found in the value of KPIs and use cases by type of business, the main finding is that none of the respondents reached the stage of a brick-and-mortar data-driven company. *In-store analytics services* are in the early stages of Rogers' (1983) model of diffusion of innovations. Three main reasons are presented: lack of technology knowledge, budget priority, and a data culture inside the companies.

Practical implications – The results should encourage scholars to further investigate the drivers accelerating the adoption of these technologies. Practitioners and solution providers should strive for improvement in the simplicity of their solutions.

Originality/value – This study is the first to analyse the level of adoption of in-store analytics from the perspective of retailers.

Keywords Brick-and-mortar, *In-store Analytics*, Technology Adoption, Retail

Article Classification: Research paper.

Introduction

The retail sector is undergoing a period of transformation and disruption (Hagberg *et al.*, 2016). Although physical retail continues to account for most of the revenue in the sector (Clement, 2019), and customers show a preference for an improved brick-and-mortar experience over online shopping (Spanke, 2020; Wilson, 2013), thousands of stores worldwide are closing down (Meisenzahl, 2021; Retail Dive, 2021). The remaining stores are going through a transformation process that some scholars refer to as the retail apocalypse (Childs *et al.*, 2020; Mende and Noble, 2019) because of the growth of e-commerce (Chiang and Dholakia, 2003).

Indeed, e-commerce has several benefits for shoppers, such as product range, product information, and convenience (Somani, 2015). For retailers, e-commerce provides full information on customer behaviour and traffic (Beri and Parminder, 2013; Bilgic and Duan, 2019). Customer traffic measurement is the key to a profitable business and has been positively correlated with sales in previous research (Anic *et al.*, 2010; Yiu and Ng, 2010). Websites are often organised like traditional shops, with virtual departments, aisles, shopping carts, and counter lanes (Huotari, 2015). By each click, all of a customer's interactions and movements are collected and digitally stored, generating a large amount of data that can be processed to increase customer knowledge and identify actions for the business, such as customer recommendations or website restructuring (Bilgic and Duan, 2019; Ramzan *et al.*, 2019).

Although brick-and-mortar store transactions are not genuinely digital, different types of technologies are available to record and measure the internal activities of a store

(Landmark and Sjøbakk, 2017; Zeng *et al.*, 2015). The evolution of the Internet of Things increasingly introduces hardware and software allowing the registration of real-world transaction data to create valuable information for businesses (Weinswig, 2017). Having access to **activity analytics** in physical stores is a key asset that allows for more fact-based decisions. Moreover, such analytics can be used to take dynamic and automatic decisions (Huotari, 2015). Customer behaviour data have the potential to raise the interest of any business, as the number of customers and their path in the store impact sales volume (Perdikaki *et al.*, 2012).

This research focuses on the perception and level of adoption of **in-store analytics services** by retailers based on a proposed service definition that delivers customer insights for physical stores. **In-store analytics is a generic term to define the technology and services that provide automated information of activity of customers and sales in a brick-and-mortar store.** This study aims to answer the following question: Are brick-and-mortar retailers leveraging in-store analytics? For this purpose, fieldwork based on interviews and a focus group of retailer representatives were conducted. Respondents explained their needs, current level of digitalisation, and their views on the benefits and value of in-store analytics. The results show the level of maturity of retailers in the usage of this technology and support two major contributions. First, it shows that physical retailing remains in the early stages of **in-store analytics** adoption, whereas the same companies are gathering and analysing customer tracking data in their online businesses. **The difference between the two scenarios shows the lack of a homogeneous data culture inside the companies of the sample.** Second, the study shows that there is no mature digital plan for retailers with respect to brick-and-mortar technologies, despite ongoing initiatives and an underlying interest in data-driven companies. Three main obstacles explain the situation: lack of technology knowledge, lack of budget priority, and the absence of a data culture. A

1
2
3 simplified plan is presented to overcome these obstacles. These contributions allow
4
5 practitioners to improve their technology and services. Furthermore, the results will
6
7 encourage researchers to analyse the value of *in-store analytics* and related technologies.
8
9

10 The remainder of this paper proceeds as follows. Section 2 sets the theoretical
11
12 background for this research, explains the value of measuring customer behaviour in
13
14 brick-and-mortar retailing and related technologies, and addresses privacy concerns.
15
16 Section 3 develops the empirical analysis, explains the research objectives, the survey
17
18 model, and the composition of the sample and the data obtained, as well as includes a
19
20 discussion of the results. Finally, in Section 4, the conclusions, limitations of the study,
21
22 and proposals for future research are presented.

30 **Theoretical background**

31 *Innovation diffusion theory*

32
33
34
35
36
37
38 There is an extant corpus of literature on technology adoption in brick-and-mortar
39
40 stores, based on several adoption model theories (Jocevski, 2020; Vakulenko *et al.*, 2018;
41
42 Wolpert and Roth, 2020). Rogers' diffusion of innovations theory (DOI) (Rogers, 1983)
43
44 is one of the most frequently used theories and is thus appropriate for an exploratory
45
46 approach to the adoption of a certain innovation (Bhattacharya, 2015; Kang *et al.*, 2015).
47
48 DOI synthesises a set of factors (relative advantage, compatibility, complexity,
49
50 trialability, and visibility) of the process of adoption, and categorises the adopters in
51
52 groups (innovators, early adopters, early majority, late majority, and laggards), according
53
54 to their moment of adopting the innovation, as the adoption process is not immediate.
55
56
57
58 DOI has been used as a theoretical framework in previous retail studies to approach
59
60

1
2
3 innovation from the perspective of retailers and their managers (Pantano and Vannucci,
4
5 2019; Tsai *et al.*, 2010).
6
7
8
9

10 11 *The business value of in-store analytics* 12

13 One of the most accepted characteristics of e-commerce, since its beginning, has
14
15 been the digital recording of interactions (Huotari, 2015), which facilitates accurate
16
17 business decisions (Chaffey and Patron, 2012; Phippen *et al.*, 2004). Bilgic and Duan
18
19 (2019, p. 175) identified, through a systematic literature review, the business value of e-
20
21 commerce data analytics, and highlighted several usages, such as ‘pricing a
22
23 product/service, designing or improving a product/service and recommending a
24
25 product/service, measuring service quality, etc.’. The goal is to increase sales through
26
27 conversion rate optimisation (CRO) (Beri and Parminder, 2013; Chaffey and Patron,
28
29 2012; Saleem *et al.*, 2019). Under the term CRO, practitioners group techniques to
30
31 improve conversion rates, which generally refer to sales per visitor (Saleem *et al.*, 2019).
32
33
34
35
36

37 The logging of transactions and interactions in the physical world requires
38
39 recording technology. Cheaper sensors, improved software algorithms, and mobile
40
41 devices (Härtfelder and Winkelmann, 2016) narrow the differences between brick-and-
42
43 mortar retailers and e-commerce merchants in terms of [activity information](#) (Mavroudis
44
45 and Veale, 2018), which leads to a better understanding of the shopping process, with
46
47 important findings for the business (Perdikaki *et al.*, 2012; Karaman, 2015). Companies
48
49 measure the level of performance of their processes by defining relevant indicators, called
50
51 key performance indicators (KPIs), which allow the measurement of the level of
52
53 achievement of specific targets (Nagyova and Pacaiova, 2009). In retail, the KPIs for the
54
55 physical world tend to match those of the online stores, even though they are limited by
56
57 the type of interaction or the deployment costs. For example, in e-commerce, it is easy to
58
59
60

1
2
3 register that a customer is viewing a product page (Bilgic and Duan, 2019), whereas in a
4
5 brick-and-mortar store, it is more difficult to track a customer's interest in specific
6
7 products in the aisles through IoT technology (Pfeiffer *et al.*, 2020). Despite such
8
9 restrictions, the incremental value is colossal. Based only on customer traffic and sales,
10
11 Perdikaki *et al.* (2012) defined relevant KPIs, such as conversion rate and basket value,
12
13 and obtained business insights that affected store labour and location decisions. Traffic
14
15 tracking can also be applied to larger areas, such as an entire high street, and can provide
16
17 information on customer preferences, specific shopping times for different items, or the
18
19 propensity to react to promotions (Betzing, 2018). Huotari (2015) conducted a literature
20
21 review of retail KPIs. He discarded the financial KPIs that focus on the financial targets
22
23 of the company, such as the level of investment, profitability, or inventory cost, to focus
24
25 on those of a non-financial nature. The research found that 42.2% of non-financial KPIs
26
27 were related to customer behaviour, such as traffic (visits), customer flow, mobility, time
28
29 spent in an area, and loyalty. Sales were used in some ratios to offer important insights
30
31 into business performance, such as the conversion rate.
32
33
34
35
36
37

38 Initially, traditional methods were used to register these data, including
39
40 questionnaires, surveys, and interviews (Das and Varshneya, 2017; Hu and Jasper, 2004;
41
42 Kesari and Atulkar, 2016). Although these methods can retrieve in-depth information on
43
44 preferences and opinions, they suffer from bias in the trustworthiness of the answers
45
46 (Newman *et al.*, 2002). In some cases, they were complemented by direct observations
47
48 that were labour-intensive (Yiu and Ng, 2010). Although these methods have been
49
50 broadly used in the past, there is no possibility of real-time usage and continuous
51
52 measurement, as they require human interaction to register the results (Dogan *et al.*,
53
54 2019).
55
56
57
58
59
60

1
2
3 Technology improves the trustworthiness of data without human labour and in real
4
5 time. Because the objective is to track the movements of customers in physical stores, the
6
7 technology must detect target individuals in the space. Different technologies and
8
9 methodologies can be used for these purposes. Table I presents a summary of the main
10
11 technologies that can be used for *in-store analytics* and related literature.
12
13
14
15
16
17
18
19
20
21
22

(TABLE I HERE)

23
24 Privacy is a major issue in tracking and profiling solutions. Although scholars
25
26 highlight the current privacy concerns (Farshidi, 2016; Groß, 2015; Nguyen, 2019; Turri
27
28 *et al.*, 2017) and laws are evolving towards the need for explicit approval to use any kind
29
30 of personal data (Betzing, 2018; Weinswig, 2017), customers are generally willing to
31
32 receive targeted information that represents their needs more accurately (Infosys, 2013;
33
34 Kerem and Ulla, 2018). Furthermore, some data can be anonymised and aggregated,
35
36 providing powerful insights and avoiding personal data privacy issues. Companies that
37
38 develop solutions must, therefore, choose between explicit user acceptance of the use of
39
40 personal data or an anonymisation process. An example of such use of anonymised
41
42 information is the Smart Steps service from Telefónica (Hong *et al.*, 2020; Telefonica,
43
44 2020). Based on a mixture of mobile network and web browsing information, it delivers
45
46 aggregated information on the demographics and preferences of visitors who were present
47
48 in a specific area at a specific time, as well as their previous and following visit locations.

Methodology and data

Design and sample

The study employed an interview-based methodology (Rowley, 2012), as it is the most widely used method in the organisational information systems and technology adoption literature (Choudrie and Dwivedi, 2005; Mingers, 2003). The methodology included semi-structured interviews (Louise and Alison, 1994), individual sessions, dual sessions, and a focus group, as the interview methodology allows for different options (Mingers, 2003).

To standardise the sample and ensure valuable answers from all respondents, participating businesses had to have at least 10 brick-and-mortar retail stores and use at least two of the following five technologies: digital signage, mobile app for customers, online analytics, Wi-Fi for customers, and people counters. Furthermore, interviewees had to occupy a specific rank in the company: chief executive officer (CEO), chief financial officer (CFO), chief marketing officer (CMO), or chief digital officer (CDO). Technical roles (operations and IT) were selected for group sessions. Companies could be from different retail sectors.

The final composition of the sample by sector and role is shown in Table II.

(TABLE II HERE).

A total of seven individual interviews, four dual interviews, and one focus group with six participants were conducted from 17 July to 31 July 2019. All sessions were conducted face-to-face. A semi-structured script was used, with the following five-point

1
2
3 agenda: introduction, brick-and-mortar digitalisation, company and role challenges,
4 relevant business KPIs, and service feedback. The first questions allowed us to
5 characterise the sample (Is there a plan in place to digitally transform your company?
6 What level of maturity do you have towards digital transformation?), while the main
7 questions were directly related to the research (What are your day-to-day challenges?
8 How useful would an in-store analytics solution be? How would you use it?).
9
10
11
12
13
14
15
16

17 A specific service definition for an in-store analytics solution was defined to receive
18 the respondents' feedback homogeneously. The service, named In-store Insights, can use
19 different sources of data from three technologies: Wi-Fi, beacons, and cameras. The
20 software gathers all the data from sensors and converts them into a set of KPIs, which are
21 then presented on a dashboard where a user can review the insights, export them, or mix
22 them with other sources to obtain information for making decisions. Participants were
23 informed that all the collected data would be anonymised to comply with the current
24 regulations on data protection and privacy. During the sessions, the service was described
25 to the participants, and they were requested to assess the value of two sets of information:
26 first, a list of KPIs that could be obtained, and second, cases where such information
27 would eventually be used in their businesses. KPIs and use cases were taken from existing
28 service definitions and success stories from the industry (Ipsos, 2017; Luenendonk, 2015;
29 SightCorp, 2020; Telefonica, 2020; Walkbase, 2020).

36
37
38
39
40
41
42
43
44
45
46
47

48 To characterise the sample, Table III shows the respondents' key declarative
49 statements on their market situation. Very different perceptions are observed. E-
50 commerce has disrupted each sector differently, and retailers focus on improved
51 experiences and bring value with specialised shop assistants and personalised and
52 segmented customer attention (Kamaladevi, 2010). The answers show that price
53 competition and product catalogues are not major concerns for the respondents; instead,
54
55
56
57
58
59
60

1
2
3 they seek to move away from transactional sales and add extra value to the customer's
4
5 experiences.

15

16 *Results*

17
18 The respondents provided structured feedback on the technologies currently in use and
19 the value of the In-store Insights service. Table IV presents the respondents' perceptions
20 of the level of digital maturity in their companies and the technologies already installed
21 in their businesses. Three main findings are presented in this table. First, there is no
22 relationship between the perception of maturity and the number of technologies, which
23 shows how abstract the concept of digital transformation is for the respondents. In
24 general, the respondents recognised that they were in the early stages of digital
25 transformation: 'We have just started a digital unit', (operations manager, restaurant); 'I
26 am more a marketing guy than a digital guy', (CMO, dental clinic); 'We don't have a
27 specific department, there is no budget or strategy', (CMO, cosmetics). Second, the only
28 technology that is present in all businesses is web analytics. Most companies are devoted
29 to obtaining and distributing the data: 'There's a person in the web department', (CMO,
30 travel agency); 'The people that did our Web send us the report', (CFO, hairdresser). This
31 finding underscores the value of customer tracking for retailers, when it is simple,
32 available, and established in an organisation. For example, a simple tool, such as Google
33 Analytics, is used by more than 29 million websites (BuiltWith, 2020). Interestingly, there
34 is no similar penetration of brick-and-mortar analytics; only a few of the respondents
35 measured customer flows with people counters and perceived the data obtained (visits) to
36 be of limited value for their businesses compared to the cost of installation. 'We would
37

58
59
60

1
2
3 only need this data in special events', (CEO, car dealer); 'We do have the technology, but
4
5 we don't use it, we don't check the data', (operations manager, household goods). Third,
6
7 the second-most used technology is Wi-Fi for customers: 'No matter the origin of the
8
9 customer, the first thing they want is the Wi-Fi password and then the room', (CMO,
10
11 hotel). Despite the evolution of mobile data plans, some businesses see this functionality
12
13 as necessary, even though they derive no analytics value from it: 'A coffee and the Wi-Fi
14
15 while the customers wait is a completely different experience', (CFO, hairdresser). None
16
17 of them use it as a proximity marketing tool or a customer tracking data source, probably
18
19 due to a lack of information on how Internet access can be converted into a source of data
20
21 and interaction.
22
23
24
25
26
27
28
29

30 (TABLE IV HERE).
31
32
33
34

35 Table V presents feedback from the interviewees on the KPIs. Two types of KPIs
36
37 were discussed with the respondents: simple KPIs, obtained directly from the sensors of
38
39 the service, and composite KPIs, which mix information with other sources. Five simple
40
41 KPIs were presented: *number of visitors*, measuring the number of customers entering the
42
43 store; *street attraction*, measuring the number of people entering the store related to the
44
45 number of people passing by the store; *frequency of visits*, providing information on the
46
47 number of times the same person enters the store; *dwelling time*, delivering the time spent
48
49 by a customer inside the store; and *In Store flows*, providing information about the
50
51 customer paths inside the store. The following were the three composite KPIs presented:
52
53 *Sales conversion*, that offers ratios using sales information and simple KPIs; *other*
54
55 *external sources*, that was presented to respondents as 'the possibility to obtain ratios
56
57 mixing sensor data with external data like weather, flight information in an airport,
58
59
60

1
2
3 information presented in digital signage screens, or stock level, as examples'; and
4
5 *comparison among stores*, that shows any of the other KPIs compared for different stores
6
7 of the same retailer. The results show distinct differences among the different kinds of
8
9 businesses. By sector, the first finding is that the number of visitors is more relevant for
10
11 businesses where there are no previous appointments and visitors can leave without a
12
13 purchase, such as cosmetics or household goods ('It would be great. I could plan and
14
15 focus my sales attendants', CMO, cosmetics). Hairdressers or restaurants do not see the
16
17 value of such information, as they convert almost every visit into a sale ('We do not need
18
19 it as most visits have an appointment', CFO, hairdresser).
20
21
22

23
24 There are three KPIs that stand out from the rest of the respondents' preferences:
25
26 street attraction, dwell time, and comparison among stores.
27
28

- 29
30 1) Street attraction represents the ratio of the number of people entering the store to
31
32 those passing by the store. The reasons for this preference vary among the
33
34 respondents, depending on the type of business: 'It would allow for a comparison
35
36 of the performance of our restaurants', (operations manager, restaurant); 'It is
37
38 really relevant when there is a new launch', (CEO, car dealer); 'It is useful in
39
40 looking for a new store location', (CEO, parapharmacy). The respondents' interest
41
42 in this measure is consistent with Graham's work (2016): Although retailers
43
44 cannot impact the density of shoppers, different attributes of the brands and spaces
45
46 can influence their attraction (Calvo-Porrall and Lévy-Mangin, 2018; Mohd-
47
48 Ramly and Omar, 2017).
49
50
51
52
53 2) Dwell time is relevant for all the respondents, although the reasons for the interest
54
55 vary by business type: 'It would allow us to optimise the services (CMO, dental
56
57 clinic); 'We could change the layout of the tables to serve more meals', (CFO,
58
59 restaurant); 'I could decide to set make-up artists depending on this', (CMO,
60

1
2
3 cosmetics). This finding is consistent with previous studies that found sales
4 conversion and dwell time to be positively related in retail stores (Hui *et al.*, 2009),
5
6 but negatively related to customer satisfaction in services, such as hotels and
7
8 restaurants (Jones and Dent, 1994; De Vries *et al.*, 2018). Interestingly, a
9
10 respondent from the restaurant business stated the opposite, in relation to their bar
11
12 area: ‘The longer people stay, the more they spend’, (operations manager,
13
14 restaurant).

- 15
16
17
18
19
20 3) The comparison among stores is relevant, as insights can be obtained about area
21
22 performance. ‘I compare today by calling and asking the sales manager. This is
23
24 not reliable’, (operations manager, household goods); ‘Paramount’ (CMO,
25
26 cosmetics). This is a major issue in the physical retail business (Li *et al.*, 2019),
27
28 as location is the main factor in customer traffic outside stores (Graham, 2016).
29
30
31
32
33

34 (TABLE V HERE)
35
36
37
38
39

40 The interviewees were then asked to indicate their level of interest in the list of
41
42 business use cases (11) that employed the KPIs. Table VI presents a summary of their
43
44 feedback, wherein we again observe differences among businesses. At the bottom of the
45
46 table, a simplified ratio between positive and negative answers highlights the overall level
47
48 of interest. *Adapt out-of-store promotions, improve stock management, and modify the*
49
50 *layout of the store* are the least relevant. *Improve stock management* clearly shows its
51
52 business-related effect as some of the businesses do not manage stock; however, it is
53
54 noteworthy for household goods stores, fashion stores, and parapharmacies. *Adapt out-*
55
56 *of-store promotions* and *modify layout of the store* are considered by the respondents to
57
58
59
60

1
2
3 be out of their control ('the car brand controls the layout', (CEO, car dealer); 'the design
4 is well defined by the corporation and no changes are made', (CMO, cosmetics)).

5
6
7 Therefore, their interest is reduced, even though store layout plays an important role in
8 sales performance (Webber *et al.*, 2018).
9

10
11
12 The respondents were more interested in customer experience, as shown by the
13 three most interesting use cases: *Adapt in-store promotions, improve service*
14 *personalisation, and measure the effect of campaigns*. 'I would like to know the amount
15 of time our sales attendant spends with each customer and the value of the sale',
16 (operations manager, household goods). The interest in creating a more personalised
17 service with better targeted promotions and measuring its impact is in line with previous
18 studies. Pantano and Timmermans (2014) and Willems *et al.* (2017) included this
19 functionality in the definition of retail and shopper-oriented technologies. Another
20 finding is apparent from looking at the topic with the least negative answers (15% of total
21 answers): *plan staff and schedule store times*. The results show the relevance of this topic
22 as one of the major cost drivers (Chuang *et al.*, 2016), even though the respondents
23 declared that they did not need automated processes to perform this activity.
24
25

31
32
33
34
35
36
37
38
39
40

41 From a sectorial perspective, there are three main findings. First, the lack of interest
42 in the banking sector in most of the use cases (only 22.7% of positive answers). 'I don't
43 see the need to know the number of visitors', (CIO, bank); 'We don't want to generate
44 attraction to the branches but increase the Web', (operations manager, bank). The banking
45 sector focuses on existing customers and online transactions, making the role of the
46 branches uncertain (Arguedas-Sanz *et al.*, 2013; Marakarkandy *et al.*, 2017; Myerson and
47 Sandbiller, 2018). Second, the data show few positive answers (24.2%) in the health and
48 wellness sectors. Most of their services are by appointment; thus, their current systems
49 may allow them access to the first level of information that reduces the value gap of
50
51
52
53
54
55
56
57
58
59
60

1
2
3 automated KPIs. Third, most positive answers come from retail shops: cosmetics stores,
4
5 household goods stores, fashion, stores car dealerships, and retail telco stores. These are
6
7 businesses where the conversion rate is the most relevant, which explains their higher
8
9 level of interest.

21 *Discussion*

22
23 All respondents claim that their companies are working on digital transformation.
24
25 However, in most cases, they imply solving short-term needs with isolated solutions
26
27 rather than building a comprehensive transformation plan. 'We talk about building the
28
29 digital transformation department in 1-2 years', (CMO, cosmetics); 'We have a master
30
31 plan for digitalisation, but we are just starting to see solutions and all we do is still
32
33 rudimentary', (CFO, restaurant). Why are all respondents in the same situation? Why are
34
35 companies running behind and what can be done to speed the process? Based on the
36
37 responses, there are three main interrelated reasons. The first reason is the limited
38
39 knowledge about and little confidence in the technology, which prevents them from
40
41 seeing a return on investment (ROI). Although they have embraced new in-store
42
43 technologies, they remain concerned about the ROI and the effort required to adopt such
44
45 technologies. For example, in the case of digital signage, the most extensive technology,
46
47 they recognise important set-up costs and the need for extra resources to manage the
48
49 contents properly, as well as important investments in tailoring the space. However, they
50
51 fail to measure whether the space configuration performs according to design. The data
52
53 collected by existing solutions are spread across the company, but a systematic analysis
54
55 of the data is not performed which makes it difficult to measure the value added by the
56
57
58
59
60

1
2
3 investment. This leads to the second reason: budget priorities. From a budget perspective,
4
5 digital transformation competes with other strategies, such as the opening of new shops
6
7 or restaurants, or even the marketing budget. If the technology and data are not used
8
9 properly in the formulation of an organisation's strategy, little value may be derived from
10
11 them. The budget allocation and limited priority lead to the third reason: there is no data
12
13 culture in the companies. None of the respondents mentioned data governance or data-
14
15 driven decisions. This analysis is consistent with the work of Gernann *et al.* (2014). In
16
17 their study, conducted through a survey of 418 top managers, they found that the potential
18
19 of analytics is not perceived by retailers; therefore, they do not invest in appropriate
20
21 levels, even though they would obtain relevant benefits of analytics deployments.
22
23 Following the classification of Rogers' DOI theory (Rogers, 1983), there are only a few
24
25 innovators in the sample. Moreover, they do not feel convinced of the value of in-store
26
27 analytics, showing that this technology is in its early stages.
28
29
30
31
32

33
34 Becoming a data-driven company brings several benefits (Santoro *et al.*, 2019),
35
36 despite being a major challenge. None of the respondents had a holistic view of data
37
38 collection and analysis. Although they are knowledgeable about online analytics, they do
39
40 not show the same concern about their physical spaces for the reasons mentioned above.
41
42 Beyond sales, they have no digitally recorded data, and some merely use manual input
43
44 from sales attendants to record traffic or customer flows. They acknowledge this lack of
45
46 data culture in the physical space and do not expect the organisation to allocate specific
47
48 resources to properly process the data, if such data need to be obtained.
49
50
51

52
53 The three barriers (lack of knowledge about the technology, lack of priority in the
54
55 budgets, and lack of data culture in the organisations) are consistent with previous studies
56
57 on data-driven companies (Olszak and Zurada, 2019) and technology acceptance models
58
59 by organisations. Technology knowledge, financial resources, and technology readiness
60

1
2
3 are frequently related to the lack of technology (Ratchford and Barnhart, 2012; Zhu *et al.*,
4
5 2004). Respondents' answers match the early stages of Rogers' DOI theory (Rogers,
6
7 1983).
8
9

10 Each of these challenges must be addressed to reach the level of a data-driven
11
12 company in the physical environment. Any action plan should tackle these three topics
13
14 together, as they are interdependent. Solving only two of these leads to a plan's failure.
15
16 If the company increases its knowledge of the technology and allocates its budget but
17
18 does not establish data management policies and data-driven decisions, the management
19
20 will consider these investments as useless. If the technology is mastered and there is a
21
22 data culture, but no budget is prioritised, it will not be possible to achieve deployment.
23
24 Finally, if there is a data culture in the company and budgets are prioritised, but there is
25
26 an unawareness about the potential of the technology, the appropriate solutions will go
27
28 unnoticed.
29
30
31
32
33

34 As an example, Figure 1 shows a potential action plan for companies to advance
35
36 towards a data-driven company. They need to become more knowledgeable about
37
38 technology, undertake pilots, and receive training. The board of directors must ensure that
39
40 the organisation believes in digital transformation through resource allocation. Finally,
41
42 they must implement a data governance model that includes the organisation, processes,
43
44 and technology.
45
46
47
48
49
50

51 (FIGURE 1 HERE).
52
53
54
55

56 To ensure that advanced technology is properly understood, practitioners and
57
58 manufacturers must simplify the technology and communicate real implementation use
59
60

1
2
3 cases and their benefits. Companies will devote more of their budgets to in-store analytics
4
5 technology if they see an ROI. Only then will companies adopt a structured approach to
6
7 their decision-making based on data (Troisi *et al.*, 2020).
8
9

10 Beyond these findings, the respondents can see the most advanced technology only
11
12 in a few selected stores. Their view of the role of physical stores in the future is much
13
14 more experiential, something that cannot be replicated in the online world. This is
15
16 consistent with previous studies (Poncin and Ben Mimoun, 2014; Garaus *et al.*, 2017).
17
18
19
20
21
22

23 **Conclusions**

24
25
26
27
28 The objective of this study was to analyse the level of acceptance of in-store analytics in
29
30 brick-and-mortar stores. The study follows an interview-based methodology, with semi-
31
32 structured questions that allow the exploration of different high-value topics for future
33
34 research. This work is relevant to the study of brick-and-mortar technologies because it
35
36 addresses in-store analytics technology from the perspective of organisations and delivers
37
38 an exploratory analysis of advanced technology and the level of interest from the retailers'
39
40 perspective. This approach is unique, as none of the previous studies on the value of in-
41
42 store analytics from a technology and customer perspective refers to the perception of
43
44 retailers or managers.
45
46
47
48

49 We highlight three major contributions of our study. First, related to our main
50
51 research question (Are brick-and-mortar retailers leveraging in-store analytics?), the
52
53 findings show that following the nomenclature of the DOI theory (Rogers, 1983), in-store
54
55 analytics technologies remain in the early stages of their adoption. Prior to
56
57 implementation, companies must know about a technology and be convinced of its value
58
59
60

1
2
3 before making deployment decisions. This will allow them to adopt organisational and
4
5 strategic decisions for the digital transformation of their stores. Furthermore, technology
6
7 knowledge must be linked with the allocation of the budget and the solid intention to
8
9 become a data-driven company. To address these three topics together, a simplified action
10
11 plan is presented, even though further research is required on how to accelerate the plan
12
13 from the point of view of technology, budget, organisation, and data management.
14
15 Technology providers and practitioners should make significant advances on how to
16
17 present technology in an easy-to-use business language and integrate in data-driven
18
19 companies to facilitate ROI analysis and confidence in the solutions. Success stories
20
21 should be replicated, and pilots should be affordable. Second, it was found that there was
22
23 no digital master plan for brick-and-mortar stores in most retailers, regardless of their size
24
25 or structure. Practitioners and scholars should focus on structured methodologies to
26
27 achieve such plans in a simple and cost-effective manner. Third, there is genuine interest
28
29 in data-driven companies, although no actions are taken to achieve such a platform on the
30
31 physical side of the business. Further research could investigate an omni-channel data-
32
33 driven framework that merges data from online and offline worlds.
34
35
36
37
38
39

40 Two interesting findings emerged from the analysis of responses by sector. First,
41
42 in-store analytics are less interesting to businesses with appointments or reservations,
43
44 where customer flows are more predictable. Second, the banking sector exhibits the
45
46 lowest interest in customer flow information because of the profound transformation of
47
48 the banking business and the priorities in their digital transformation (Cuesta *et al.*, 2015;
49
50 Vasiljeva and Lukanova, 2016).
51
52
53

54 This study had several limitations. The main factor was the number of respondents.
55
56 As the sample comprised only one respondent per business type, the results may be biased
57
58 by the knowledge or personality of the respondents, and some results may not represent
59
60

1
2
3 the general trend in businesses. Nevertheless, consistent results were found for most
4
5 questions, as shown in the results section, including the core question of our research.
6
7
8 Despite the exploratory nature of the study, it brings interesting new insights that link
9
10 with and extend previous research. The second limitation is the definition of service. In-
11
12 store analytics is a term that does not have a single definition or scope in the industry.
13
14 However, this study narrowed the definition to a specific service, In-store Insights, to
15
16 allow a comparison of answers and obtain significant findings. Finally, the number of
17
18 different sectors in the sample is appropriate for an exploratory study. Nevertheless,
19
20 specific work per sector should be done in future research to support or negate our
21
22 findings with more evidence.
23
24
25

26
27 This study opens several avenues for research as, to the best of our knowledge, there
28
29 are no studies on in-store customer tracking technology adoption model that address the
30
31 adoption status and the method to accelerate the implementation of such technologies.
32
33 Further work should consider the three major barriers that respondents have revealed in
34
35 the research: lack of data culture, lack of technology knowledge, and lack of budget
36
37 priority. We urge scholars to focus on technology adoption models that can explain and
38
39 confirm the exploratory findings of this study. We recommend that practitioners focus on
40
41 simplifying the solution from a user experience perspective, clearly showing the added
42
43 values based on the KPIs that can be obtained automatically, and how to apply these
44
45 solutions to the specific use cases of each company. Finally, scholars and practitioners
46
47 should develop practical methodologies to evaluate the digital transformation maturity of
48
49 organisations and generate action plans leading to execution.
50

Table I: Technologies used for in-store analytics

Technology	Description	Use cases presented in previous works	Limitations	References
RFID (Radio Frequency Identification)	Short range radio technology frequently used for supply chain control and goods tracking. Implemented inside trolleys and shopping baskets that are tracked thanks to layout antennas.	Analyse shopping paths. Improve fitting room interaction. Analyse purchase probability based on dwell time. Analyse dwell time. Modify paths to draw attention to less visited areas of the store	Only measures people with basket or trolleys. No customer opt-in, only anonymous data can be used.	Fujino <i>et al.</i> , 2014; Landmark and Sjøbakk, 2017; Larson <i>et al.</i> , 2005; Takai and Yada, 2010; Vukovic <i>et al.</i> , 2012
Bluetooth Sensors	Radio technology available in most mobile devices. The tracking solution track bluetooth signals from customers' phones	Analyse customer behaviour inside a shopping mall.	No customer opt-in, only anonymous data. Only Bluetooth enabled phones are detected.	Oosterlinck <i>et al.</i> , 2017
Beacons	Battery powered devices emitting a Bluetooth Low Energy (BLE) unique identifier. A mobile application can read this signal and check on a cloud database the position of the beacon	Analyse shopping paths. Improve user interactions. Analyse customer behaviour. Attitude towards beacons from consumers. Indoor positioning system.	Customers must have the appropriate App and Bluetooth enabled in their phones. Expensive installations for customer tracking, as the accuracy of beacons is limited and requires a dense network of sensors.	Betzing, 2018; Dogan <i>et al.</i> , 2019; Pierdicca <i>et al.</i> , 2015; Sturari <i>et al.</i> , 2016; Thamm <i>et al.</i> , 2016; Triantafyllou <i>et al.</i> , 2017
Audio and visual Beacons	Instead of using radio, audio beacons use sound waves beyond the hearing threshold to trigger the mobile application logic, based on microphone of Bluetooth. Visual beacons are camera based and use imperceptible changes of light.	Technical and regulatory analysis.		Mavroudis and Veale, 2018
Wi-Fi	Scanning from Wi-Fi Access Points (APs) of the customer devices.	Pedestrian and cyclists monitoring. Customer tracking inside a mall. Indoor positioning system. Optimizing Store Layout. Detecting visited areas.	No customer opt-in, only anonymous data. Limitations of accuracy.	Abedi <i>et al.</i> , 2015; Bai <i>et al.</i> , 2014; Carrera <i>et al.</i> , 2018; Fukuzaki <i>et al.</i> , 2015; Hwangbo <i>et al.</i> , 2017; Zeng <i>et al.</i> , 2015
Computer Vision	Usage of image processing to detect customer movements.	Detecting potentially suspicious behaviours in shopping malls. Customer instore tracking. Analyse purchasing behaviour.	Complex algorithms or manual work to be done. No customer opt-in, only anonymous data.	Arroyo <i>et al.</i> , 2015; Celikkan <i>et al.</i> , 2011; Merad <i>et al.</i> , 2016; Oosterlinck <i>et al.</i> , 2017; Quintana <i>et al.</i> , 2016; Wu <i>et al.</i> , 2015

Table III: Business situation

Sector	Company Business	Market Situation (declarative)
Specialized retail	Travel agency	It is a mature market. Most of it has gone online. It requires advanced in-store experiences.
	Cosmetics	The business requires specialized shop assistants. The testing of products is a key element for sales.
	Household goods	The attraction to the store is key. They handle a catalogue too broad that complicates the experience.
Banking	Bank	The number of branches has dramatically diminished. The business is moving to online. The reputation of banks is not high.
	Financial Services	The business requires skilled financial advisors.
Hotels	Hotel	Most of the bookings are handled through digital platforms. Customer experience is the key element of the service.
Restaurants	Restaurant	Home delivery is changing the market.
Fashion	Clothing	It is a mature and segmented market, that requires to address perfectly target segment needs.
Car dealers	Car dealer	As the brands fix the layout and technology, the difference lies in the human interaction (sales specialist).
Retail Telco	Retail Telco	It is a price driven, mature market. The reduction of waiting times and the product rotation are key elements to sell.
Health and wellness	Dental Clinic	Price competition and omnichannel are the key elements of the business.
	Parapharmacy	It is a growing sector that requires expert sales attendants.
	Hairdressing	It is a highly competitive business, where the marketing is basically through word of mouth.
